## INVOLUTORY QUARTIC TRANSFORMATIONS IN SPACE OF FOUR DIMENSIONS

BY  
NINA ALDERTON

§1. Cayley in his paper "On the Rational Transformation between two Spaces"<sup>1</sup> gives a general discussion of the quadric transformation between two planes and the cubo-cubic transformation between two spaces. The cubic transformation in space was further studied by F. R. Morris<sup>2</sup> who gives an analytic treatment of the cases in which the Jacobian, the sextic curve whose points go into lines by means of this transformation, breaks up into curves of lower degree, one or more of which are straight lines. A synthetic treatment of the general case of the cubic space transformation is given by D. N. Lehmer<sup>3</sup> in his paper "On Combinations of Involutions," and of six of the special cases by Elizabeth J. Easton.<sup>4</sup>

§2. A discussion of the general involutory quartic transformation in space of four dimensions has been given by P. H. Schoute<sup>5</sup> in an article, "La Surface de Jacobi d'un système lineaire d'hyperquadriques  $Q^3_2$  dans l'espace  $E^4$  à quatre dimensions." The writer was not acquainted with this article when work upon the present paper was begun and consequently began with a general consideration of the involutory transformation by means of four hyperquadrics. Schoute makes his transformation with respect to a pencil of hyperquadrics and defines the transform  $P'$  of the point  $P$  as being the intersection of the polar spaces of  $P$  with respect to the triple infinity of hyperquadrics of the pencil. This is equivalent, however, to using four hyperquadrics, for four independent hyperquadrics determine the pencil. The present paper gives the discussion of the general involutory quartic transformation with respect to four hyperquadrics, as originally planned, before going on to a consideration of the cases in which the Jacobian, now a surface, breaks up into

surfaces of lower degree including at least one plane. Although it has seemed advisable to examine the subject analytically as well as synthetically to a considerable extent, the synthetic treatment only will be presented in most cases in this paper.

## §3.

## NOTATION

The exponent of the symbol of a surface will be used to denote the infinitude of points on the surface and the subscript to denote the degree of the surface; thus  $S_2^3$  designates a quadric hyper-surface.

## §4.

## DEFINITIONS

1. All of the 3-spaces through a line form what we shall call an axial pencil of 3-spaces. All of the 3-spaces through a plane form a plane pencil of 3-spaces. There are  $\infty^2$  3-spaces in an axial pencil and  $\infty$  in a plane pencil.

2. Harmonic 3-spaces of a plane pencil are four 3-spaces which are cut by any line in four harmonic points.

3. The polar 3-space of a point  $P$  with respect to a hyperquadric is the locus of a point which is the fourth harmonic to  $P$  and the two points in which any line through  $P$  cuts the hyperquadric.

4. The simplex of reference in 4-space is a figure bounded by five 3-spaces. The five 3-spaces intersect two at a time in ten planes, three at a time in ten lines, and four at a time in five points which are the vertices of the simplex.

## §5.

## PRELIMINARY THEOREMS

1. In a plane pencil (§4, 1) of 3-spaces, if four planes are cut by one line in four harmonic points they are cut by every line in four harmonic points.

*Proof.*—Upon any line  $p$  take four harmonic points. These points together with the plane of the plane-pencil determine four harmonic 3-spaces; for, cut across the plane-pencil by any 3-space through  $p$ . We then have an axial pencil of planes and we know that planes corresponding to four harmonic points of the line are four harmonic planes which are cut by any line in four harmonic points. Since this is true in any 3-space through  $p$ , we see that any line cuts the four 3-spaces corresponding to four harmonic points of the line in four harmonic points. Hence as a point  $P$  moves along  $p$ , the polar 3-spaces of  $P$  with respect to four hyperquadrics will form four projective plane-pencils. Similarly, as  $P$  moves over a plane, the polar 3-spaces of  $P$  will form four projective axial pencils.

2. There are  $\infty^2$  lines cutting four planes in 4-space. *Proof:* Call the planes  $a_1, a_2, a_3, a_4$ . If we pass a 3-space through  $a_1$ , it will cut  $a_2, a_3$ , and  $a_4$  in three lines. There will be  $\infty$  lines in the 3-space cutting these three lines, and these lines will also cut  $a_1$ , since they lie in the same 3-space with  $a_1$ . Hence in every 3-space through  $a_1$ , there will be  $\infty$  lines cutting  $a_1, a_2, a_3$  and  $a_4$ . But there are  $\infty$  3-spaces about  $a_1$  (§4, 1) and consequently  $\infty^2$  lines cutting  $a_1, a_2, a_3$  and  $a_4$ .

## CASE I

GENERAL TRANSFORMATION BY MEANS OF FOUR  
HYPERQUADRICS

§6. We may set up an involutory one-to-one correspondence between the points of 4-space by means of four arbitrarily chosen hyperquadrics. To a point  $P$  corresponds a point  $P'$ , the intersection of the four polar 3-spaces of  $P$  with respect to the four hyperquadrics. Since the polar 3-spaces of  $P'$  must all pass through  $P$  and since four 3-spaces can intersect, in general, in only one point, the point  $P$  also corresponds to the point  $P'$  and we have an involutory, one-to-one correspondence.

§7. Thus, in general, to a point  $P$  will correspond a point  $P'$ , but there are certain points to which correspond a whole line of points. The locus of such a point is the Jacobian. We shall show that

*Theorem I.* The locus of all points whose transform is a line is a surface of the tenth degree in 4-space,  $J^2_{10}$ . (2, §3). Proof: Let the four hyperquadrics be

$$\begin{aligned} A &= \sum a_i x_i x_j = 0 \\ B &= \sum b_{ij} x_i x_j = 0 \\ C &= \sum c_{ij} x_i x_j = 0 \\ D &= \sum d_{ij} x_i x_j = 0 \end{aligned} \quad \left[ \begin{array}{l} i = 1 \dots 5 \\ j = 1 \dots 5 \end{array} \right]$$

The polar 3-spaces of a point  $P$  with respect to  $A, B, C$  and  $D$  are then

$$\begin{aligned} x'_1 A_1 + x'_2 A_2 + x'_3 A_3 + x'_4 A_4 + x'_5 A_5 &= 0 \\ x'_1 B_1 + x'_2 B_2 + x'_3 B_3 + x'_4 B_4 + x'_5 B_5 &= 0 \\ x'_1 C_1 + x'_2 C_2 + x'_3 C_3 + x'_4 C_4 + x'_5 C_5 &= 0 \\ x'_1 D_1 + x'_2 D_2 + x'_3 D_3 + x'_4 D_4 + x'_5 D_5 &= 0 \end{aligned}$$

Ordinarily these four 3-spaces will intersect in a point. If, however, the equations are linearly dependent they will intersect in a line. The condition for this is that the matrix of the coefficients be of rank three; i.e. that all of the four-rowed determinants of the matrix vanish. Hence from the matrix

$$\left| \begin{array}{ccccc} A_1 & A_2 & A_3 & A_4 & A_5 \\ B_1 & B_2 & B_3 & B_4 & B_5 \\ C_1 & C_2 & C_3 & C_4 & C_5 \\ D_1 & D_2 & D_3 & D_4 & D_5 \end{array} \right|$$

we shall have five four-rowed determinants equal to zero. Each of these equations represents a quartic hypersurface. The Jacobian is the locus of points lying on all five of these hyperquartics. The hyperquartic we get by omitting the fourth column and the one we get by omitting the fifth column will intersect in a surface of degree sixteen,  $S^2_{16}$ . But they have in common the matrix formed of the first three columns which represents a surface of the sixth degree through which the other hyperquartics do not pass. Hence the Jacobian, the surface through which all five hyperquartics pass, is a  $J^2_{10}$ .

§8. *Theorem II.* The lines which are the transforms of the points of  $J^2_{10}$  form a ruled hypersurface,  $j^3_{15}$ .

Proof: If we denote by  $X=0$ ,  $Y=0$ ,  $Z=0$ ,  $W=0$ , and  $V=0$  the hyperquadrics of the matrix of §7 which we get by omitting the first column, then the second, etc., we know that the equation of the Jacobian hypersurface, which is made up of the lines which are the transforms of points of  $J^2_{10}$ , may be found by equating to zero the determinant of the partial derivatives of  $X$ ,  $Y$ ,  $Z$ ,  $W$  and  $V$  with respect to  $x_1$ ,  $x_2$ ,  $x_3$ ,  $x_4$  and  $x_5$ ; thus

$$j = \begin{vmatrix} X_1 & X_2 & X_3 & X_4 & X_5 \\ Y_1 & Y_2 & Y_3 & Y_4 & Y_5 \\ Z_1 & Z_2 & Z_3 & Z_4 & Z_5 \\ W_1 & W_2 & W_3 & W_4 & W_5 \\ V_1 & V_2 & V_3 & V_4 & V_5 \end{vmatrix} = 0$$

Each element of this determinant is of degree three in  $x_1$ ,  $x_2$ ,  $x_3$ ,  $x_4$  and  $x_5$  and hence the equation represents a hypersurface of degree fifteen which we shall designate as  $j^3_{15}$ .

§9. Thus we see that the points of 4-space go by this transformation into other points with the exception of points on a  $J^2_{10}$  whose points transform into the lines of a ruled  $j^3_{15}$ .

§10. It seems at first thought as though there might be points in 4-space whose polar 3-spaces meet in planes, but this is not true in general. The condition for this would be that the matrix of the coefficients of the four polar 3-spaces of §7 be of rank two. The forty cubic hypersurfaces obtained by setting each three-rowed determinant equal to zero would all have to pass through the points which transform into planes. Taking the first three rows of the matrix,

$$\begin{vmatrix} A_1 & A_2 & A_3 & A_4 & A_5 \\ B_1 & B_2 & B_3 & B_4 & B_5 \\ C_1 & C_2 & C_3 & C_4 & C_5 \end{vmatrix}$$

the three cubic hypersurfaces represented by columns 1, 2, 3; 1, 2, 4; and 1, 2, 5 intersect in a cubic surface and a curve. The other seven cubic hypersurfaces represented by this matrix will not pass through the cubic surface but will pass through the curve. Similarly, taking the matrix

$$\begin{vmatrix} B_1 & B_2 & B_3 & B_4 & B_5 \\ C_1 & C_2 & C_3 & C_4 & C_5 \\ D_1 & D_2 & D_3 & D_4 & D_5 \end{vmatrix}$$

we find that the ten cubic hypersurfaces whose equations are the different three-rowed determinants of the matrix set equal to zero pass through another curve. Two curves do not, in general, intersect in 4-space and therefore the twenty cubic hypersurfaces so far examined have no points in common and hence the forty have none. Consequently there are no points whose transforms are planes when the hyperquadrics are unrelated.

§11. *Theorem III.* If a point  $P$  moves along a line  $p$ , its corresponding point  $P'$  moves along a quartic curve in 4-space.

Proof: As the point  $P$  moves along the line  $p$ , its polar 3-spaces with respect to the four hyperquadrics revolves about four planes forming what we shall call plane pencils of 3-spaces. These four plane pencils are projective pencils for there is a one-to-one correspondence between the points of  $p$  and the 3-spaces of the four plane pencils, and to four harmonic points of the line correspond four harmonic 3-spaces of the pencils. (2, §4, and Theorem I, §5.) The locus of the intersection of corresponding 3-spaces of the four projective plane pencils will be the transform of the line  $p$ . If we cut across the plane pencils by a 3-space, we have four projective axial pencils of planes in a 3-space. Four and only four sets of corresponding planes of these pencils meet in points, (Reye, *Geometrie der Lage*, vol. 2, XII, p. 93), so there are four points of the locus in every 3-space and hence the transform of the line  $p$  is a quartic curve in 4-space. The single infinitude of points of the curve corresponds to the single infinitude of points of the line  $p$ .

§12. *Theorem IV.* If the point  $P$  moves over a 3-space, the corresponding point  $P'$  moves over a quartic hypersurface.

Proof: If the point  $P$  moves over a 3-space, the polar 3-spaces of  $P$  with respect to the four hyperquadrics revolve about four points forming what we shall call four points of 3-spaces. There will be a triple infinitude of points  $P'$  corresponding to the triple infinitude of points  $P$  and hence points  $P'$  lie on a hyper-surface. In order to find the degree of this hypersurface, cut across it by a line. Transforming, the line goes into a quartic curve, as we have just seen, and the hypersurface back into the 3-space, giving off also the  $j^3_{15}$ . The hypersurface must give off the  $j^3_{15}$  when transformed, for it contains  $j^2_{10}$ , since the 3-space of which it is the transform cuts all of the lines of  $j^3_{15}$ . The points of the hypersurface which do not transform into lines but into points will go back into the points of the 3-space on account of the involutory relation between the points under this transformation. But the quartic curve cuts the 3-space in four points. Therefore the line cuts the hypersurface in four points and it is a quartic hypersurface.

§13. *Theorem V.* If  $P$  moves over a plane, its corresponding point  $P'$  moves over an  $S_6^2$ .

Proof: The plane may be considered as the intersection of two 3-spaces,  $R_1$  and  $R_2$ . When we transform, these two 3-spaces go into two quartic hypersurfaces which intersect in a surface  $S^2_{16}$ . But we have seen (§12) that every quartic hypersurface which is the transform of a 3-space must pass through  $J^2_{10}$ . Hence  $J^2_{10}$  is a part of  $S^2_{16}$  and the remaining part is an  $S_6^2$  which is then the transform of the plane.

§14. *Theorem VI.* The multiplicity of lines of  $j^3_{15}$  through points of  $J^2_{10}$  and the multiplicity of points of  $J^2_{10}$  on lines of  $j^3_{15}$  is four.

Proof: If  $p'$  is a line which is the transform of a point  $P$  of  $J^2_{10}$ , then the polar 3-spaces of all points of  $p'$  will pass through  $P$ . Ordinarily the four polar 3-spaces

of points of  $p'$  intersect in only one point and this must be the point  $P$ . Since  $P$  is always a common point of four polar 3-spaces of points of  $p'$ , in order for  $p'$  to transform into a quartic curve it must go into four lines passing through  $P$ . But  $P$  is any point of  $J^2_{10}$  and hence the Jacobian must be a surface of  $j^3_{15}$  of multiplicity four. The points of  $p'$  all go into the point  $P$  except four points whose transforms are the four lines through  $P$ . Hence there are four points of  $J^2_{10}$  on every line of  $j^3_{15}$ , or the lines of  $j^3_{15}$  cut  $J^2_{10}$  in four points.

§15. Summary.—The principal facts which have been established concerning the general involutory quartic transformation in 4-space are: that lines go into quartic curves, planes into surfaces of the sixth degree, and 3-spaces into quartic hypersurfaces; also, that the locus of points whose transforms are lines is a surface of the tenth degree, and the lines which are the transforms of these points form a hypersurface of the fifteenth degree.

## CASE II

### ONE FUNDAMENTAL HYPERQUADRIC IS A SPACE-PAIR

§16. (a) In Case I the four hyperquadrics of the transformation were perfectly general. We shall now consider the case in which one of the hyperquadrics  $A$  is a space-pair whose 3-spaces intersect in a plane  $a_1$ . It is evident that we may still set up a one-to-one correspondence between the points of 4-space, for ordinarily to a point  $P$  will correspond a point  $P'$ , the intersection of polar 3-spaces of  $P$  with respect to  $B$ ,  $C$  and  $D$  and the 3-space conjugate with respect to the 3-spaces of  $A$  to that determined by  $P$  and the plane  $a_1$ .

§17. The polar 3-space with respect to  $A$  of a point  $P$  on  $a_1$  is indeterminate and hence to such a point corresponds the line of intersection of the polar 3-spaces with respect to  $B$ ,  $C$  and  $D$ . Hence  $a_1$  is a part of  $J^2_{10}$  and

*Theorem VII.* The Jacobian is a plane and an  $S^2_9$  when one of the fundamental hyperquadrics is a space-pair.

§18. *Theorem VIII.* The Jacobian hypersurface is an  $S^3_3$  and an  $S^3_{12}$  when one of the fundamental hyperquadrics is a space-pair.

Proof: The transforms of points of  $a_1$  are lines of  $j^3_{15}$ . As  $P$  moves over  $a_1$ , the polar 3-spaces of  $P$  revolve about three lines forming three projective axial pencils. (1, §5). Now three projective axial pencils of 3-spaces intersect in a hypersurface of the third degree, for if we cut across them by any 3-space we have three points of planes intersecting in a cubic surface. Hence  $j^3_{15}$  breaks down into a hypersurface of the third degree and one of the twelfth degree.

§19. (b) If the two 3-spaces of  $A$  coincide; i.e. if  $A$  is composed of two coincident 3-spaces we cannot set up an involutory relation between points of 4-space, for the polar 3-space of any point will be  $A$  itself and the points of 4-space will transform into those of a 3-space.

## CASE III

## TWO FUNDAMENTAL HYPERQUADRICS ARE SPACE-PAIRS

§20. (a) Suppose  $A$  and  $B$  are the two space-pairs and  $\alpha_1$  and  $\alpha_2$ , the planes of intersection of the pairs of 3-spaces of  $A$  and  $B$  respectively, have only a point in common. It is evident that we may still set up an involutory one-to-one correspondence between the points of 4-space. The planes  $\alpha_1$  and  $\alpha_2$  are part of  $J^2_{10}$  and we have the theorem

*Theorem IX.* The Jacobian is composed of two planes and an  $S^2_8$  when two of the fundamental hyperquadrics are space-pairs.

§21. The planes  $\alpha_1$  and  $\alpha_2$  both go into cubic hypersurfaces of  $j^3_{15}$ . Hence

*Theorem X.* The Jacobian hypersurface is composed of two  $S^3_3$ 's and an  $S^3_9$  when two of the fundamental hyperquadrics are space-pairs.

§22. There is a plane lying on both of the cubic hypersurfaces and hence forming part of their intersection; namely the transform of the point of intersection of the two planes  $\alpha_1$  and  $\alpha_2$ . This point transforms into a plane since its polar 3-spaces with respect to  $A$  and  $B$  are indeterminate, and its transform is then the intersection of its polar 3-spaces with respect to  $C$  and  $D$ .

§23. A line  $l$  cutting either  $\alpha_1$  or  $\alpha_2$  will transform into a line and a cubic curve. Suppose it cuts  $\alpha_1$ . The line  $l_1$  is the transform of the point where the given line  $l$  cuts  $\alpha_1$ . To get the transform of the rest of  $l$ , allow the point  $P$  to move along  $l$ . The point  $P$  and the plane  $\alpha_1$  always determine the same 3-space and hence all points of  $l$  have the same polar 3-space with respect to  $A$ . The polar 3-spaces of points of  $l$  with respect to  $B$ ,  $C$  and  $D$  form the three projective plane pencils of 3-spaces and these intersect in lines of a ruled  $S^2_3$ , for if we cut across them by a 3-space we have three projective axial pencils whose corresponding planes intersect in points of a cubic curve. The polar 3-space of points of  $l$  with respect to  $A$  will cut this  $S^2_3$  in a twisted cubic. Hence  $l$  transforms into a line and a twisted cubic lying in the polar 3-space with respect to  $A$  of points of  $l$ . Similarly, a line cutting  $\alpha_2$  will transform into a line and a twisted cubic lying in the polar 3-space with respect to  $B$  of points of the line.

§24. A line  $l$  cutting both  $\alpha_1$  and  $\alpha_2$  will transform into two lines  $l_1$  and  $l_2$  and a conic  $C_2$  lying in the plane of intersection of the two polar 3-spaces of points of  $l$  with respect to  $A$  and  $B$ .

§25. Other lines which do not transform into quartic curves are those lying on  $\alpha_1$  (or  $\alpha_2$ ). A line lying on  $\alpha_1$  (or  $\alpha_2$ ) and not passing through  $P_1$ , the intersection of  $\alpha_1$  and  $\alpha_2$ , becomes an  $S^2_3$ , the locus of intersections of corresponding 3-spaces of three projective plane pencils of 3-spaces. If the line passes through this point  $P_1$ , also, the cubic surface breaks up into a plane, the transform of  $P_1$ , and an  $S^2_2$  lying in the polar 3-space with respect to  $B$  (or  $A$ ) of points of the line.

§26. The surface  $S_6^2$  which is the transform of a plane has two lines lying on it, the transforms of the points of intersection of the plane with  $\alpha_1$  and  $\alpha_2$ . If these two points coincide at  $P_1$ , the  $S_6^2$  breaks down into a plane which is the transform of  $P_1$  and an  $S_5^2$ . Further degeneration of the  $S_6^2$  occurs when the plane intersects  $\alpha_1$  (or  $\alpha_2$ ) and both  $\alpha_1$  and  $\alpha_2$  in lines.

§27. A 3-space containing  $\alpha_1$  (or  $\alpha_2$ ) will transform into a ruled cubic hypersurface which is the transform of  $\alpha_1$  (or  $\alpha_2$ ) and the 3-space which is the polar of points of the 3-space with respect to  $A$  (or  $B$ ).

(b) Now suppose  $A$  and  $B$  are so related that  $\alpha_1$  and  $\alpha_2$  intersect in a line  $L_3$ ; i.e. that all of the 3-spaces of  $A$  and  $B$  pass through  $L_3$ . Then we have the theorem

*Theorem XI.* The Jacobian is composed of three planes and a  $S_7^2$  when space-pairs  $A$  and  $B$  have a line in common.

Proof: The points of  $L_3$  transform into the planes of a planed hyperquadric which are the intersections of two plane pencils of polar 3-spaces of points of  $L_3$  with respect to  $C$  and  $D$ . Hence the plane  $\alpha_1$  (or  $\alpha_2$ ) will transform into the planes of a planed hyperquadric and  $\infty^2$  lines of the 3-space which is the polar of points of  $\alpha_1$  (or  $\alpha_2$ ) with respect to  $B$  (or  $A$ ). Hence  $\alpha_1$  and  $\alpha_2$  are still parts of  $J_{10}^2$  and have a line lying on them whose points transform into planes. Now  $\alpha_1$  and  $\alpha_2$  determine a 3-space since they have a line in common. Points of this 3-space will have a single polar 3-space with respect to  $A$  and a single polar 3-space with respect to  $B$  and these two 3-spaces will intersect in a plane  $\beta_3$  passing through  $L_3$ . The polar 3-space of points of  $\beta_3$  with respect to both  $A$  and  $B$  will be the 3-space determined by  $\alpha_1$  and  $\alpha_2$ , and this 3-space will cut the polar 3-spaces with respect to  $C$  and  $D$  in lines. Hence  $\beta_3$  is also a part of  $J_{10}^2$ , as are the planes  $\alpha_1$  and  $\alpha_2$ .

§28. *Theorem XII.* The Jacobian hypersurface is composed of a planed hyperquadric counted twice, three 3-spaces, and an  $S_3^3$  when the four 3-spaces of  $A$  and  $B$  have a line in common.

Proof: The plane  $\alpha_1$  (or  $\alpha_2$ ) goes into a hyperquadric which is the transform of  $L_3$  and the 3-space which is the polar 3-space with respect to  $B$  (or  $A$ ) of points of  $\alpha_1$  (or  $\alpha_2$ ). The plane  $\beta_3$  goes into the 3-space determined by  $\alpha_1$  and  $\alpha_2$ . Hence three 3-spaces and a hyperquadric counted twice will be part of the  $j_{15}^3$ . It should be noted that a line on  $J_{10}^2$  whose transform is counted twice is a triple line on  $J_{10}^2$ ; in this case the three planes  $\alpha_1$ ,  $\alpha_2$ , and  $\beta_3$  pass through  $L_3$ .

§29. Again, lines which have a special position with respect to  $\alpha_1$  and  $\alpha_2$  will not transform as usual into quartic curves. Any line cutting  $L_3$  will transform into a plane and a conic lying in the plane of intersection of the two polar 3-spaces of points of the line with respect to  $A$  and  $B$ . The transform of a plane cutting  $L_3$  or passing through  $L_3$  will be a degenerate  $S_6^2$ . The 3-space determined by  $\alpha_1$  and  $\alpha_2$  will go into the planed hyperquadric and the two 3-spaces which are the remainder of the transforms of  $\alpha_1$  and  $\alpha_2$ . All points of the 3-space not on  $\alpha_1$  or  $\alpha_2$  go into points of  $\beta_3$ .

§30. (c) Suppose one of the 3-spaces of  $B$  (or  $A$ ) passes through the plane of intersection of the 3-spaces of  $A$  (or  $B$ ). If  $A$  and  $B$  are so related that one of the

3-spaces,  $R_3$  of  $B$ , passes through  $a_1$ , then  $a_1$  and  $a_2$  determine  $R_3$  and must intersect in a line  $L_3$  as in (b). The plane  $\beta_3$  will now coincide with  $\alpha_1$ , the intersection of the conjugate 3-space of  $R_3$  with respect to  $A$  and  $R_3$  itself, since it is self-conjugate with respect to  $B$ . Hence

*Theorem XIII.* The Jacobian is composed of a single plane, a double plane, and an  $S_7^2$  when one of the 3-spaces of  $B$  (or  $A$ ) passes through  $a_1$  (or  $a_2$ ).

§31. *Theorem XIV.* The Jacobian hypersurface is composed of a planed hyperquadric counted twice, a single 3-space, a double 3-space and an  $S_8^3$ . The single 3-space is the conjugate with respect to  $A$  of  $R_3$  and the double one is  $R_3$  itself.

§32. (d) If  $a_1$  and  $a_2$  coincide in  $a_1$ , the points of 4-space go into points of  $a_1$  and we no longer have a one-to-one correspondence.

#### CASE IV

#### THREE FUNDAMENTAL HYPERQUADRICS ARE SPACE-PAIRS

§33. (a) Suppose  $A$ ,  $B$  and  $C$  are space-pairs and their planes,  $\alpha_1$ ,  $\alpha_2$ , and  $\alpha_3$  respectively, have only points in common.

*Theorem XV.* The Jacobian is composed of three planes and an  $S_7^2$  when three of the fundamental hyperquadrics are space-pairs. The planes  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$  which form part of the  $J_{10}^2$  intersect two at a time in three points  $P_1$ ,  $P_2$  and  $P_3$ . These points transform into planes. There are two such points on each of the three planes.

§34. *Theorem XVI.* The Jacobian hypersurface is composed of three hypercubics and an  $S_8^3$  when three of the fundamental hyperquadrics are space-pairs.

The three hypercubics are transforms of the planes  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$ .

§35. If  $\alpha_1$  and  $\alpha_2$  intersect in  $P_3$ ,  $\alpha_2$  and  $\alpha_3$  in  $P_1$ , and  $\alpha_3$  and  $\alpha_1$  in  $P_2$ , then a line such as the one joining  $P_1$  with any point of  $\alpha_1$  transforms into a plane and two lines. A plane through two of the points  $P_1$ ,  $P_2$ ,  $P_3$ , say  $P_1$  and  $P_2$ , will go into two planes which are the transforms of  $P_1$  and  $P_2$ , another plane which is the transform of the other points of the line  $P_1 P_2$ , and a cubic surface lying in the 3-space conjugate to that determined by the plane to be transformed and  $\alpha_3$ . The plane  $P_1$ ,  $P_2$ ,  $P_3$ , goes into six planes.

§36. (b) Suppose two of the three planes  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$ , say  $\alpha_1$  and  $\alpha_2$ , intersect in a line  $L_3$ .

*Theorem XVII.* The Jacobian is composed of four planes and an  $S_6^2$  when two of the three fundamental space-pairs  $A$ ,  $B$  and  $C$  have a line in common.

The four planes are the planes  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$  and the plane  $\beta_3$  which is the intersection of the two polar 3-spaces of points of the 3-space determined by  $\alpha_1$  and  $\alpha_2$  with respect to  $A$  and  $B$ .

§37. *Theorem XVIII.* The Jacobian hypersurface is composed of three 3-spaces, a planed hyperquadric counted twice, a hypercubic and an  $S_5^3$  when two of the three fundamental space-pairs  $A, B, C$  have a line in common.

§38. (c) Suppose the three fundamental space-pairs  $A, B, C$  are so related that a 3-space  $R_3$  of  $B$  passes through  $\alpha_1$ . This implies that  $\alpha_1$  and  $\alpha_2$  have a line  $L_3$  in common.

*Theorem XIX.* The Jacobian is composed of two planes, a double plane, and an  $S_6^2$  when three of the fundamental hyperquadrics are space-pairs and a 3-space of one of them passes through the plane of another.

This is true since two of the four planes of Theorem XVII now coincide in  $\alpha_1$ . (Compare Theorem XIII.)

§39. *Theorem XX.* The Jacobian hypersurface is composed of one single 3-space, one double 3-space, a planed hyperquadric counted twice, a hypercubic and an  $S_5^3$  when three of the fundamental hyperquadrics are space-pairs and a 3-space of one of them passes through a plane of another.

§40. (d) The three fundamental space-pairs may be so related that  $A$  and  $B$  have a line  $L_3$  in common and  $B$  and  $C$  have a line  $L_1$  in common. In this case

*Theorem XXI.* The Jacobian is composed of six planes and an  $S_4^2$  when  $A$  and  $B$  have a line in common and  $B$  and  $C$  have a line in common.

The six planes are  $\alpha_1, \alpha_2, \alpha_3$ , the plane  $\beta_3$  which is the intersection of the two polar 3-spaces of points of the 3-space  $R'$  determined by  $\alpha_1$  and  $\alpha_2$  with respect to  $A$  and  $B$ , the plane  $\beta_1$  which is the intersection of the two polar 3-spaces of points of the 3-space  $R''$  determined by  $\alpha_2$  and  $\alpha_3$  with respect to  $B$  and  $C$ , and the plane  $\beta_2$  which is the intersection of the polar 3-space of points of  $R'$  with respect to  $A$  and the polar 3-space of points of  $R''$  with respect to  $C$ .

§41. The lines  $L_3$  and  $L_1$  intersect since they both lie in  $\alpha_2$  and this point  $P$  which lies on each of the three planes  $\alpha_1, \alpha_2$  and  $\alpha_3$  transforms into a 3-space. It should be noted that the planes  $\beta_1, \beta_2$  and  $\beta_3$  also pass through  $P$  and hence a point on  $J_{10}^2$  whose transform is a 3-space of  $j_{15}^3$  counted three times has six sheets of the surface passing through it. The 3-space into which all points of  $\alpha_1$  except those lying on  $L_3$  transform is the 3-space determined by  $\alpha_2$  and  $\alpha_3$ , and similarly for  $\alpha_3$ . This may be shown by taking  $A, B$  and  $C$  as space-pairs through three planes of the simplex of reference. (4, §4.) The 3-spaces determined by  $\alpha_1$  and  $\alpha_2$  and by  $\alpha_2$  and  $\alpha_3$  are then two of the five faces of the simplex. Hence in this case

*Theorem XXII.* The Jacobian hypersurface is composed of one triple 3-space, four double 3-spaces and an  $S_4^3$  when the three fundamental space-pairs  $A, B$  and  $C$  are so related that  $A$  and  $B$  have a line in common and  $B$  and  $C$  have a line in common. Two of the double 3-spaces are of course the 3-spaces determined by  $\alpha_1$  and  $\alpha_2$  and by  $\alpha_2$  and  $\alpha_3$ .

§42. Any line lying in  $\alpha_2$  and not passing through  $P$  transforms into three planes since it cuts both  $L_1$  and  $L_3$ . If it passes through  $P$  it transforms into a 3-space and a plane.

§43. (e) Let one of the 3-spaces  $R_3$  of  $B$  pass through  $a_1$  while  $a_2$  and  $a_3$  still have a line  $L_1$  in common.

*Theorem XXIII.* The Jacobian is composed of four single planes, a double plane and an  $S_4^2$  when one of the 3-spaces of  $B$  passes through  $a_1$  and  $B$  and  $C$  have a line in common.

This is due to the coincidence of two of the planes of Theorem XXI, the double plane being the plane  $a_1$ .

§44. *Theorem XXIV.* The Jacobian hypersurface is composed of two triple 3-spaces, two double 3-spaces, a single 3-space and an  $S_4^3$  when one of the 3-spaces of  $B$  passes through  $a_1$  and  $B$  and  $C$  have a line in common.

The 3-space  $R_3$  is one of the triple 3-spaces and the plane determined by  $a_2$  and  $a_3$  is the single 3-space.

§45. (f) Suppose one of the 3-spaces  $R_3$  of  $B$  passes through  $a_1$  and one of the 3-spaces  $R_5$  of  $C$  passes through  $a_2$ . Then

*Theorem XXV.* The Jacobian is composed of two single planes, two double planes, and an  $S_4^2$  when one of the 3-spaces of  $B$  passes through  $a_1$  and one of the 3-spaces of  $C$  passes through  $a_2$ . The two double planes are  $a_1$  and  $a_2$  while  $a_3$  is one of the single planes.

§46. *Theorem XXVI.* The Jacobian hypersurface is composed of a triple 3-space, four double 3-spaces, and an  $S_4^3$  when one of the 3-spaces of  $B$  passes through  $a_1$ , and one of the 3-spaces of  $C$  passes through  $a_2$ .

The 3-spaces  $R_3$  and  $R_5$  are double 3-spaces.

§47. (g) Suppose one of the 3-spaces,  $R_3$ , of  $B$  passes through  $a_1$  and the other,  $R_4$ , passes through  $a_3$ .

*Theorem XXVII.* The Jacobian is composed of two single planes, two double planes and an  $S_4^2$  when one 3-space of  $B$  passes through  $a_1$  and the other through  $a_3$ .

The planes  $a_1$  and  $a_3$  are double planes while  $a_2$  is now a single plane.

§48. *Theorem XXVIII.* The Jacobian hypersurface is composed of a triple 3-space, four double 3-spaces, and an  $S_4^3$  when one 3-space of  $B$  passes through  $a_1$  and the other through  $a_3$ .  $R_3$  and  $R_4$  are double 3-spaces.

§49. (h) Let the planes  $a_1$ ,  $a_2$ , and  $a_3$  intersect in lines two at a time.

*Theorem XXIX.* The Jacobian is composed of six planes and an  $S_4^2$  when the planes  $a_1$ ,  $a_2$  and  $a_3$  intersect two at a time in lines.

Call the intersection of  $a_1$  and  $a_2$   $L_3$ , the intersection of  $a_2$  and  $a_3$   $L_1$ , and the intersection of  $a_3$  and  $a_1$   $L_2$ . The planes  $a_1$ ,  $a_2$  and  $a_3$  now lie in a 3-space  $R$  and intersect in a point  $P$  so the lines  $L_1$ ,  $L_2$  and  $L_3$  are concurrent. The 3-space  $R$  will have conjugate 3-spaces with respect to  $A$ ,  $B$  and  $C$  which will intersect two at a time in planes  $\beta_3$ ,  $\beta_1$  and  $\beta_2$  which together with planes  $a_1$ ,  $a_2$  and  $a_3$  are the six planes of the  $J_{10}^2$ .

§50. *Theorem XXX.* The Jacobian hypersurface is composed of one triple 3-space, four double 3-spaces and an  $S_4^3$  when the planes  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$  intersect two at a time in lines. This is true since the plane  $\alpha_1$  transforms into lines of  $\beta_1$  and the three 3-spaces which are the transforms of  $L_2$  and  $L_3$ ,  $\alpha_2$  into lines of  $\beta_2$  and the three 3-spaces which are the transforms of  $L_1$  and  $L_3$ , and  $\alpha_3$  into lines of  $\beta_3$  and the three 3-spaces which are the transforms of  $L_1$  and  $L_2$ .

§51. The transform of points of  $R$  with respect to  $A$ ,  $B$  and  $C$  will be three 3-spaces intersecting in a line  $L_4$ . Hence the planes  $\beta_1$ ,  $\beta_2$  and  $\beta_3$  all transform into  $R$ , the transform of points of  $L_4$ , which is then one of the double 3-spaces of  $J_{15}^3$ . (§28.) Points of this line  $L_4$  will transform into planes of  $R$ . Hence there are four lines,  $L_1$ ,  $L_2$ ,  $L_3$  and  $L_4$ , whose transforms are 3-spaces of planes.

§52. Any line in  $\alpha_1$ ,  $\alpha_2$  or  $\alpha_3$  will transform into three planes if it does not pass through  $P$ , for it will cut two of the lines  $L_1$ ,  $L_2$  and  $L_3$ . If it does pass through  $P$  it will transform into a 3-space and a plane through one of the lines  $L_1$ ,  $L_2$  or  $L_3$ . The planes  $\beta_1$ ,  $\beta_2$  and  $\beta_3$  all pass through  $L_4$  and hence any line in  $\beta_1$ ,  $\beta_2$  or  $\beta_3$  will transform into two planes since it cuts  $L_4$  and either  $L_1$ ,  $L_2$  or  $L_3$ .

§53. (i) Suppose one of the 3-spaces  $R_3$  of  $B$  in (h) passes through  $\alpha_1$ . The planes  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$  now all lie in  $R_3$  and hence  $R_3$  passes through  $\alpha_3$ . Hence part of  $J_{10}^2$  is  $\alpha_1$  taken twice,  $\alpha_3$  taken twice,  $\alpha_2$  and  $\beta_2$  or

*Theorem XXXI.* The Jacobian is composed of two double planes, two single planes, and an  $S_4^2$  when a 3-space  $R_3$  of  $B$  passes through  $\alpha_1$  and  $\alpha_3$ .

§54. *Theorem XXXII.* The Jacobian hypersurface is composed of one triple 3-space, four double 3-spaces, and an  $S_4^3$  when a 3-space  $R_3$  of  $B$  passes through  $\alpha_1$  and  $\alpha_2$ .

The 3-space  $R_3$  is one of the double 3-spaces.

§55. (j) If  $L_2$  coincides with  $L_1$ , then  $L_3$  also coincides with  $L_1$ . In this case all of the points of 4-space go into points of  $L_1$  and we no longer have a one-to-one correspondence.

## CASE V

### THE FOUR FUNDAMENTAL HYPERQUADRICS ARE SPACE-PAIRS

§56. (a) Let  $A$ ,  $B$ ,  $C$  and  $D$  be four space-pairs any two of which have only a point in common. The planes  $\alpha_1$ ,  $\alpha_2$ ,  $\alpha_3$ , and  $\alpha_4$  of  $A$ ,  $B$ ,  $C$  and  $D$  respectively are planes of the  $J_{10}^2$ . Hence

*Theorem XXXIII.* The Jacobian is composed of four planes and an  $S_6^2$  when the four fundamental hyperquadrics are space-pairs intersecting in pairs in points.

§57. *Theorem XXXIV.* The Jacobian hypersurface is composed of four hypercubics and an  $S_3^3$  when the four fundamental hyperquadrics are space-pairs intersecting in pairs in points.

§58. There are  $\infty^2$  lines cutting  $a_1, a_2, a_3$  and  $a_4$ . (2, §5.) Any one of these lines will transform into four lines which are rulings of the  $j^3_{15}$ . It cuts  $J^2_{10}$  four times so the point into which the remainder of the line transforms is the point through which the four lines pass. Hence the four lines are concurrent. Lines cutting only three of the planes  $a_1, a_2, a_3$  and  $a_4$  also transform into four lines but these lines are not concurrent.

§59. (b) Suppose the 3-spaces of  $A$  and  $B$  have a line  $L_3$  in common.

*Theorem XXXV.* The Jacobian is composed of five planes and an  $S_5^2$  when two of the four fundamental space-pairs have a line in common.

The planes are  $a_1, a_2, a_3$  and  $a_4$  and the plane  $\beta_3$  which transforms into lines of the 3-space determined by  $a_1$  and  $a_2$ .

§60. *Theorem XXXVI.* The Jacobian hypersurface is composed of three 3-spaces, a planed hyperquadric counted twice, two cubic hypersurfaces and an  $S_2^3$ .

§61. (c) Suppose a 3-space  $R_3$  of  $B$  passes through  $a_1$ .

*Theorem XXXVII.* The Jacobian is composed of three single planes, a double plane, and an  $S_5^2$  when a 3-space of  $B$  passes through  $a_1$ .

The double plane is the plane  $a_1$ .

§62. *Theorem XXXVIII.* The Jacobian hypersurface is composed of a single 3-space, a double 3-space, a planed hyperquadric counted twice, and an  $S_2^3$ , when a 3-space of  $B$  passes through  $a_1$ . The double 3-space is  $R_3$ .

§63. (d) Suppose  $A$  and  $B$  have a line  $L_3$  in common and  $C$  and  $D$  a line  $L_2$  in common.

*Theorem XXXIX.* The Jacobian is composed of six planes and an  $S_4^2$  when  $A$  and  $B$  have a line in common and  $C$  and  $D$  have a line in common.

The planes are  $a_1, a_2, a_3, a_4$  and also  $\beta_3$  and  $\beta_2$  which transform into the 3-spaces determined by  $a_1$  and  $a_2$  and by  $a_3$  and  $a_4$  respectively.

§64. *Theorem XL.* The Jacobian hypersurface is composed of two hyperquadrics counted twice and seven 3-spaces when  $A$  and  $B$  have a line in common and  $C$  and  $D$  have a line in common.

§65. (e) If the lines  $L_2$  and  $L_3$  of (d) intersect in a point  $P$ , then every point in 4-space transforms into the point  $P$  and we no longer have a one-to-one correspondence.

§66. (f) Suppose the space-pairs  $A, B$ , and  $C$  are so related that  $A$  and  $B$  have a line  $L_3$  in common and  $B$  and  $C$  have a line  $L_1$  in common.

*Theorem XLI.* The Jacobian is composed of seven planes and an  $S_4^2$  when  $A$  and  $B$  have a line in common and  $B$  and  $C$  have a line in common.

The planes are  $a_1, a_2, a_3$  and  $a_4$  and the planes  $\beta_1, \beta_2$  and  $\beta_3$  of Theorem XXI.

§67. *Theorem XLII.* The Jacobian hypersurface is composed of a triple 3-space, four double 3-spaces, a single 3-space, and a hypercubic.

§68. (g) Suppose the space-pairs  $A$  and  $B$  have a line  $L_3$  in common,  $B$  and  $C$  a line  $L_1$  in common, and  $C$  and  $D$  a line  $L_2$  in common.

*Theorem XLIII.* The Jacobian breaks down into the ten planes of the simplex of reference (4, §4) when the four fundamental hyperquadrics are space-pairs and three pairs of them intersect in lines. This is more easily seen analytically. Take as the fundamental space-pairs

$$A = x^2_1 - bx^2_2 = 0$$

$$B = x^2_1 - cx^2_3 = 0$$

$$C = x^2_3 - dx^2_4 = 0$$

$$D = x^2_4 - ex^2_5 = 0$$

The Jacobian turns out to be, in addition to the planes  $a_1$ ,  $a_2$ ,  $a_3$  and  $a_4$ , the planes

$$\begin{array}{ccccccc} \left\{ \begin{array}{l} x_2=0 \\ x_3=0 \end{array} \right. & \left\{ \begin{array}{l} x_1=0 \\ x_4=0 \end{array} \right. & \left\{ \begin{array}{l} x_3=0 \\ x_5=0 \end{array} \right. & \left\{ \begin{array}{l} x_1=0 \\ x_5=0 \end{array} \right. & \left\{ \begin{array}{l} x_2=0 \\ x_4=0 \end{array} \right. & \text{and} & \left\{ \begin{array}{l} x_2=0 \\ x_4=0 \end{array} \right. \end{array}$$

§69. *Theorem XLIV.* The Jacobian hypersurface breaks down into the five faces of the simplex of reference counted three times when the four fundamental hyperquadrics are space-pairs and the three pairs of them intersect in lines.

The equation of the Jacobian hypersurface turns out to be

$$x^3_1 \cdot x^3_2 \cdot x^3_3 \cdot x^3_4 \cdot x^3_5 = 0$$
